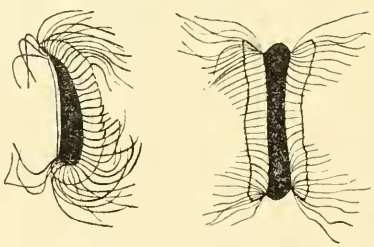
The eggs of Anopheles mediopunctatus Theobald

by

C. Bonne.

The eggs of *Anopheles mediopunctatus* Theobald are very curious. The massive part of it is slightly curved. The air sacks on both sides are inserted more towards the convexity. They are large, reaching nearly both of the poles of the eggs, but near the extremity they bend over towards the concav side of the egg. They are provided with ribs and every rib is continued in a filament. These filaments form together a fringe on both sides of the egg, the elements of which are longest near the poles of the egg. The surface of the egg itself is smooth.



Eggs of *Anopheles mediopunctatus* Theobald.
